

Alert from the NDEWS Web Monitoring Team: Online mentions of Methallylescaline

What was found? Analysis indicates that Reddit discussion on methallylescaline has been increasing since late 2023.

What is Methallylescaline? Methallylescaline is a synthetic analog of mescaline. It is a 5-HT receptor agonist.

How is it being discussed? Methallylescaline is discussed primarily in the context of its psychedelic effects, which are frequently compared to those of mescaline. Reddit users particularly note many strong visual effects. Several posts and comments mention nausea, vomiting, and an uncomfortable "body load" (a collection of effects that can include a sense of unease, shortness of breath, and a feeling of overstimulation) as negative side effects. Discussions often warn of methallylescaline's steep dose-response curve, where small dosage changes can dramatically alter the experience. Some users experiment with polysubstance use where methallylescaline is combined with other substances like etizolam.
